PHP PATTERNS

MVC

The most common architectural pattern used in the popular PHP frameworks like Yii and Laravel.

 The model-view-controller (MVC) pattern lets you break up code into objects.

Models serve as a data access layer where data is fetched and returned in formats usable in which they can be used in the application.

Controllers handle requests, process data returned from Models and load as views to send a response.

And views are display templates that are sent in response to the browser.

PHP Standards Recommendations

In WS we use some Standards to improve the coding.

In MVC we use PSR-4: Autoloader, instead use many require statement, we use auto loading function to reference faster all class we need. In MVC section we will study more about how use.

It's not entire necessary in World Skills, but for more knowledge to future development you can access the link: http://www.php-fig.org/psr/
